Part 1: Probability models of Language

### The Language Modeling problem

#### Setup

Assume a (finite) vocabulary of words:  $V = \{killer, crazy, clown\}$ 

```
Use \mathcal V to construct an infinite set of sentences \mathcal V^+=\{ \\ \text{clown, killer clown, crazy clown,} \\ \text{crazy killer clown, killer crazy clown,} \\ \dots \\ \}
```

▶ A sentence is **defined** as each  $s \in V^+$ 

# The Language Modeling problem

#### Data

Given a training data set of example sentences  $s \in \mathcal{V}^+$ 

### Language Modeling problem

Estimate a probability model:

$$\sum_{s \in \mathcal{V}^+} p(s) = 1.0$$

- ightharpoonup p(clown) = 1e-5
- ightharpoonup p(killer) = 1e-6
- p(killer clown) = 1e-12
- p(crazy killer clown) = 1e-21
- p(crazy killer clown killer) = 1e-110
- p(crazy clown killer killer) = 1e-127

# Probability models of language

#### Question

- lacktriangle Given a finite vocabulary set  ${\cal V}$
- $lackbox{ We want to build a probability model } P(s) ext{ for all } s \in \mathcal{V}^+$
- **But** we want to consider sentences s of each length  $\ell$  separately.
- ▶ Write down a new model over  $\mathcal{V}^+$  such that  $P(s \mid \ell)$  is in the model
- ▶ **And** the model should be equal to  $\sum_{s \in \mathcal{V}^+} P(s)$ .
- Write down the model

$$\sum_{s\in\mathcal{V}^+}P(s)=\dots$$

Backoff Smoothing with Discounting

**Evaluating Language Models** 

Event Space for *n*-gram Models

# *n*-gram Models

### Google *n*-gram viewer

Directly count using a training data set of sentences:  $w_1, \ldots, w_n$ :

$$p(w_1,\ldots,w_n)=\frac{c(w_1,\ldots,w_n)}{N}$$

- c is a function that counts how many times each sentence occurs
- ▶ *N* is the sum over all possible  $c(\cdot)$  values
- Problem: does not generalize to new sentences unseen in the training data.
- ▶ What are the chances you will see a sentence: crazy killer clown crazy killer?
- ► In NLP applications we often need to assign non-zero probability to previously unseen sentences.

Apply the Chain Rule: the unigram model

$$p(w_1,\ldots,w_n) \approx p(w_1)p(w_2)\ldots p(w_n)$$
  
=  $\prod_i p(w_i)$ 

Big problem with a unigram language model

p(the the the the the the the) > p(we must also discuss a vision .)

### Apply the Chain Rule: the bigram model

$$p(w_1,...,w_n) \approx p(w_1)p(w_2 | w_1)...p(w_n | w_{n-1})$$

$$= p(w_1) \prod_{i=2}^n p(w_i | w_{i-1})$$

#### Better than unigram

p(the the the the the the the) < p(we must also discuss a vision .)

### Apply the Chain Rule: the trigram model

$$p(w_1,...,w_n) \approx p(w_1)p(w_2 \mid w_1)p(w_3 \mid w_1, w_2)...p(w_n \mid w_{n-2}, w_{n-1})$$

$$p(w_1)p(w_2 \mid w_1) \prod_{i=3}^n p(w_i \mid w_{i-2}, w_{i-1})$$

### Better than bigram, but ...

p(we must also discuss a vision .) might be zero because we have not seen p(discuss  $\mid$  must also)

#### Maximum Likelihood Estimate

### Using training data to learn a trigram model

- Let c(u, v, w) be the count of the trigram u, v, w, e.g. c(crazy, killer, clown).  $P(u, v, w) = \frac{c(u, v, w)}{\sum_{u,v,w} c(u, v, w)}$
- Let c(u, v) be the count of the bigram u, v, e.g. c(crazy, killer).  $P(u, v) = \frac{c(u, v)}{\sum_{u, v} c(u, v)}$
- For any u, v, w we can compute the conditional probability of generating w given u, v:

$$p(w \mid u, v) = \frac{c(u, v, w)}{c(u, v)}$$

For example:

$$p(clown \mid crazy, killer) = \frac{c(crazy, killer, clown)}{c(crazy, killer)}$$

How many probabilities in each *n*-gram model

► Assume  $V = \{killer, crazy, clown, UNK\}$ 

### Question

How many unigram probabilities: P(x) for  $x \in \mathcal{V}$ ?

4

How many probabilities in each *n*-gram model

► Assume  $V = \{killer, crazy, clown, UNK\}$ 

#### Question

How many bigram probabilities: P(y|x) for  $x, y \in \mathcal{V}$ ?

$$4^2 = 16$$

How many probabilities in each n-gram model

► Assume  $V = \{killer, crazy, clown, UNK\}$ 

### Question

How many trigram probabilities: P(z|x,y) for  $x,y,z\in\mathcal{V}$ ?

$$4^3 = 64$$

#### Question

- ightharpoonup Assume |V| = 50,000 (a realistic vocabulary size for English)
- What is the minimum size of training data in tokens?
  - If you wanted to observe all unigrams at least once.
  - If you wanted to observe all trigrams at least once.

125,000,000,000,000 (125 Ttokens)

Some trigrams should be zero since they do not occur in the language,  $P(the \mid the, the)$ .

But others are simply unobserved in the training data,  $P(idea \mid colourless, green)$ .

# Handling tokens in test corpus unseen in training corpus

### Assume closed vocabulary

In some situations we can make this assumption, e.g. our vocabulary is ASCII characters

### Interpolate with unknown words distribution

We will call this *smoothing*. We combine the *n*-gram probability with a distribution over unknown words

$$P_{\mathrm{unk}}(w) = \frac{1}{V_{\mathrm{all}}}$$

 $V_{
m all}$  is an estimate of the vocabulary size including unknown words.

#### Add an <unk> word

Modify the training data L by changing words that appear only once to the  $\langle \text{unk} \rangle$  token. Since this probability can be an over-estimate we multiply it with a probability  $P_{\text{unk}}(\cdot)$ .

Part 3: Smoothing Probability Models

#### Language models

n-grams for Language Modeling Handling Unknown Tokens

Smoothing *n*-gram Models
Interpolation: Jelinek-Mercer Smoothing
Backoff Smoothing with Discounting

**Evaluating Language Models** 

Event Space for *n*-gram Models

# Interpolation: Jelinek-Mercer Smoothing

$$P_{ML}(w_i \mid w_{i-1}) = \frac{c(w_{i-1}, w_i)}{c(w_{i-1})}$$

- ►  $P_{JM}(w_i \mid w_{i-1}) = \lambda P_{ML}(w_i \mid w_{i-1}) + (1 \lambda)P_{ML}(w_i)$ where,  $0 \le \lambda \le 1$
- ► Jelinek and Mercer (1980) describe an elegant form of this **interpolation**:

$$P_{JM}(ngram) = \lambda P_{ML}(ngram) + (1 - \lambda)P_{JM}(n - 1gram)$$

What about  $P_{JM}(w_i)$ ? For missing unigrams:  $P_{JM}(w_i) = \lambda P_{ML}(w_i) + (1 - \lambda) \frac{\delta}{V}$  $0 < \delta \le 1$ 

# Interpolation: Finding $\lambda$

$$P_{JM}(ngram) = \lambda P_{ML}(ngram) + (1 - \lambda)P_{JM}(n - 1gram)$$

- Deleted Interpolation (Jelinek, Mercer)
   compute λ values to minimize cross-entropy on held-out data which is deleted from the initial set of training data
- ▶ Improved JM smoothing, a separate  $\lambda$  for each  $w_{i-1}$ :

$$P_{JM}(w_i \mid w_{i-1}) = \lambda(w_{i-1})P_{ML}(w_i \mid w_{i-1}) + (1 - \lambda(w_{i-1}))P_{ML}(w_i)$$

# Backoff Smoothing with Discounting

► Absolute Discounting (aka abs) (Ney, Essen, Kneser)

$$P_{abs}(y \mid x) = \begin{cases} \frac{c(xy) - D}{c(x)} & \text{if } c(xy) > 0\\ \alpha(x)P(y) & \text{otherwise} \end{cases}$$

• where  $\alpha(x)$  is chosen to make sure that  $P_{abs}(y \mid x)$  is a proper probability

$$\alpha(x) = 1 - \sum_{y} \frac{c(xy) - D}{c(x)}$$

# Backoff Smoothing with Discounting

Backoff Smoothing with Discounting

### **Evaluating Language Models**

Event Space for *n*-gram Models

# **Evaluating Language Models**

- ▶ So far we've seen the probability of a sentence:  $P(w_0, ..., w_n)$
- ▶ What is the probability of a collection of sentences, that is what is the probability of an unseen test corpus *T*
- ▶ Let  $T = s_0, ..., s_m$  be a test corpus with sentences  $s_i$
- ightharpoonup T is assumed to be separate from the training data used to train our language model P(s)
- $\blacktriangleright$  What is P(T)?

# Evaluating Language Models: Independence assumption

- $ightharpoonup T = s_0, \dots, s_m$  is the text corpus with sentences  $s_0$  through  $s_m$
- ▶  $P(T) = P(s_0, s_1, s_2, ..., s_m)$  but each sentence is independent from the other sentences
- $P(T) = P(s_0) \cdot P(s_1) \cdot P(s_2) \cdot \ldots \cdot P(s_m) = \prod_{i=0}^m P(s_i)$
- $P(s_i) = P(w_0^{(i)}, \dots, w_{n_i}^{(i)})$  which can be any *n*-gram language model
- A language model is better if the value of P(T) is higher for unseen sentences T, we want to maximize:

$$P(T) = \prod_{i=0}^{m} P(s_i)$$

# Evaluating Language Models: Computing the Average

- ► However, *T* can be any arbitrary size
- $\triangleright$  P(T) will be lower if T is larger.
- ► Instead of the probability for a given T we can compute the average probability.
- ightharpoonup M is the total number of tokens in the test corpus T:

$$M = \sum_{i=0}^{m} \operatorname{length}(s_i)$$

▶ The average *log* probability of the test corpus *T* is:

$$\frac{1}{M}\log_2 \prod_{i=0}^m P(s_i) = \frac{1}{M} \sum_{i=0}^m \log_2 P(s_i)$$

### Evaluating Language Models: Perplexity

▶ The average *log* probability of the test corpus *T* is:

$$\ell = \frac{1}{M} \sum_{i=0}^{m} \log_2 P(s_i)$$

- ightharpoonup Note that  $\ell$  is a negative number
- lacktriangle We evaluate a language model using *Perplexity* which is  $2^{-\ell}$

# **Evaluating Language Models**

### Question

Show that:

$$2^{-\frac{1}{M}\log_2\prod_{i=0}^m P(s_i)} = \frac{1}{\sqrt[M]{\prod_{i=0}^m P(s_i)}}$$

# **Evaluating Language Models**

### Question

What happens to  $2^{-\ell}$  if any *n*-gram probability for computing P(T) is zero?

# Evaluating Language Models: Perplexity

Simon Fraser University

Part 5: Event space in Language Models

### Trigram Models

► The trigram model:

```
P(w_1, w_2, ..., w_n) = P(w_1) \times P(w_2 \mid w_1) \times P(w_3 \mid w_1, w_2) \times P(w_4 \mid w_2, w_3) \times ... P(w_i \mid w_{i-2}, w_{i-1}) ... \times P(w_n \mid w_{n-2}, ..., w_{n-1})
```

- ▶ Notice that the length of the sentence *n* is variable
- What is the event space?

- ▶ Let  $V = \{a, b\}$  and the language L be  $V^*$
- ► Consider a unigram model: P(a) = P(b) = 0.5
- ► So strings in this language *L* are:

a stop 
$$0.5$$
b stop  $0.5^2$ 
aa stop  $0.5^2$ 
bb stop  $0.5^2$ 

▶ The sum over all strings in *L* should be equal to 1:

$$\sum_{w\in L}P(w)=1$$

▶ But P(a) + P(b) + P(aa) + P(bb) = 1.5 !!

- What went wrong?
  We need to model variable length sequences
- Add an explicit probability for the stopsymbol:

$$P(a) = P(b) = 0.25$$

$$P(\mathsf{stop}) = 0.5$$

▶ P(stop) = 0.5,  $P(a \text{ stop}) = P(b \text{ stop}) = 0.25 \times 0.5 = 0.125$ ,  $P(aa \text{ stop}) = 0.25^2 \times 0.5 = 0.03125$  (now the sum is no longer greater than one)

Notice that the probability of any sequence of length n is  $0.25^n \times 0.5$ Also there are  $2^n$  sequences of length n

$$\sum_{w} P(w) = \sum_{n=0}^{\infty} 2^{n} \times 0.25^{n} \times 0.5$$
$$\sum_{n=0}^{\infty} 0.5^{n} \times 0.5 = \sum_{n=0}^{\infty} 0.5^{n+1}$$
$$\sum_{n=1}^{\infty} 0.5^{n} = 1$$

With this new stop symbol we can show that  $\sum_{w} P(w) = 1$ Using  $p_s = P(\text{stop})$  the probability of any sequence of length n is  $p(n) = p(w_1, \dots, w_{n-1}) \times p_s(w_n)$ 

$$\sum_{w} P(w) = \sum_{n=0}^{\infty} p(n) \sum_{w_{1},...,w_{n}} p(w_{1},...,w_{n})$$

$$= \sum_{n=0}^{\infty} p(n) \sum_{w_{1},...,w_{n}} \prod_{i=0}^{n} p(w_{i})$$

$$egin{aligned} \sum_{w_1,...,w_n}\prod_i p(w_i) = \ \sum_{w_1}\sum_{w_2}\dots\sum_{w_n} p(w_1)p(w_2)\dots p(w_n) = 1 \end{aligned}$$

$$\sum_{w_1} \sum_{w_2} \dots \sum_{w_n} p(w_1) p(w_2) \dots p(w_n) = 1$$

$$\sum_{n=0}^{\infty} p(n) = \sum_{n=0}^{\infty} p_s (1 - p_s)^n$$

$$= p_s \sum_{n=0}^{\infty} (1 - p_s)^n$$

$$= p_s \frac{1}{1 - (1 - p_s)} = p_s \frac{1}{p_s} = 1$$
